

ENG720: Research Proposal

Title: To Be Confirmed
Author: Shane Reynolds
Supervisor: Charles Yeo
Degree: Bachelor of Engineering (Honours)

1 Introduction

1.1 Background

Interconnected power systems are comprised of power generating units and energy storage systems, which are connected to transmission and distribution networks such that generated power can service load demand. A typical single line diagram of a power network can be seen in Figure 1. The left hand side of the diagram shows thermal generation units such as coal and nuclear, in addition to renewable sources of generation like wind and solar. The right hand side of the figure shows the distribution network and the consumers of generated energy: industry and households.

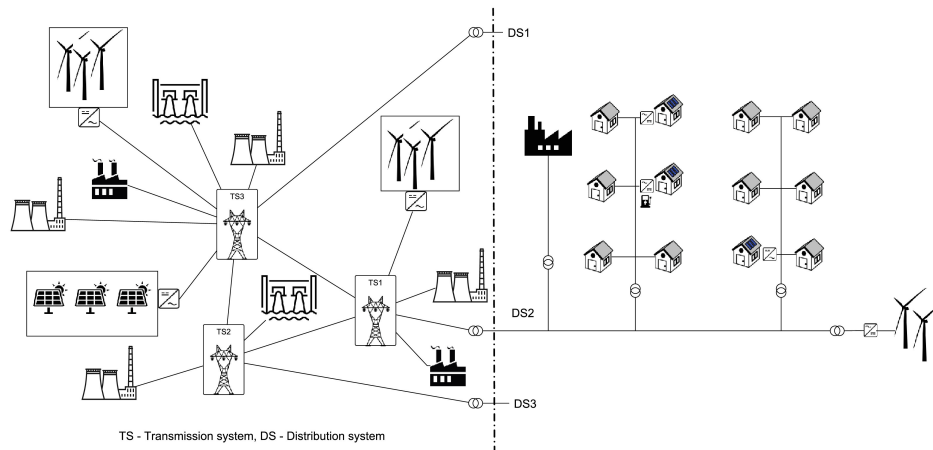

Figure 1: A single line diagram of a typical power system taken from [1]. The image shows points of generation from thermal and renewable sources, and the subsequent supply of generated energy to meet load demand through the transmission and distribution network.

Successful operation of interconnected power systems requires total load demand to be matched with total generation, taking into account power losses involved with generation, transmission, and distribution [2]. A single thermal generator system can be thought of, in its simplest form, as a prime mover (turbine) and a synchronous machine, as depicted in Figure 2.

Figure 2: Perhaps the simplest way to think of a thermal generation unit is as a prime mover (turbine), and a synchronous machine. This image was taken from [2].

The prime mover provides mechanical torque, T_{mech} , which drives the synchronous machine producing the electrical energy that supplies electrical loads connected to the system. The synchronous machine creates a torque which opposes T_{mech} . It is called electrical torque and is denoted as T_{elec} . Letting α represent angular velocity of the generator rotating mass, and I be the rotating mass moment of inertia, Newton's second law states:

$$\sum T_i = I\alpha \quad (1)$$

Equation (1) shows that when T_{mech} equals T_{elec} the system is said to be in a steady state, with zero angular acceleration, and constant rotation at some angular velocity ω . Now, if $T_{mech} > T_{elec}$, then the angular velocity ω of the system will speed up. Conversely, if $T_{mech} < T_{elec}$ then the angular velocity ω will slow down. What makes this situation interesting is that at any point in time the total electrical load demand will fluctuate stochastically. System controllers, such as the Australian Energy Market Operator (AEMO) and Power and Water Corporation (PWC), can forecast daily demand profiles with some reliability using historical data. An example of historical daily demand profiles are shown in Figure 3.

Figure 3: Weekday energy demand profile in South Australia during summer [3].

Forecasts provide a starting point that AEMO and PWC can use for estimating generation needed to meet demand for a given time. Unfortunately forecasts are not perfect and unpredicted load can appear on the system, or worse, generation assets could be disconnected from the network. Mismatches in generation and demand lead to small imbalances between T_{mech} and T_{elec} , and thus a resulting in a change to angular velocity ω and the network frequency [4].

Australia's electricity network is designed to operate at a frequency of 50Hz. In the majority of network scenarios AEMO's desired operating range for frequency is 49.85Hz and 50.15Hz [5]. The PWC Network Technical Code for the Northern Territory states that under normal operating conditions frequency should be maintained in the range 49.80Hz to 50.20Hz [6]. Operation outside of specified ranges can cause damage to electrical equipment. Sustained over or under frequency will generally cause protection systems to remove equipment from the network, as will sudden large frequency deviations. If the disconnections are uncontrolled then this can create further imbalance to the electrical network. In order to correct these deviations, system controllers use generators which are referred to as regulating units. A regulating generator is a generator that has the capacity to increase or decrease mechanical torque T_{mech} allowing the system controller to arrest changing frequency and restore the system to stable operating conditions. An example of regulation arresting a frequency disturbance, and the subsequent restoration of the system can be seen in Figure 4.

1.2 Significance

Why is this topic significant to you? Why should others be interested in it? You might find it helpful to think about what led you to undertake research in this area.

You might also consider how scholars in the field discuss its importance. In what ways is your understanding of its significance similar or different?

2 Research Aims and Questions

Now state explicitly the hypothesis you aim to test. Make references to the items listed in the Reference section that back up your arguments for why this is a reasonable hypothesis to test, for example the work of Knuth.

Explain what you expect will be accomplished by undertaking this particular project. Moreover, is it likely to have any other applications?

Constructing a clear and focused research question (or questions) is crucial to producing a good research proposal and, more importantly, shaping the direction of your research. The question indicates exactly what you want to explore and allows the reader to assess whether or not your project is viable. It also gives the reader a sense of the arguments or findings that you might produce in response. This allows them to provide you with useful feedback on the direction of your research.

The criteria for a good research question vary from one field of study to another. It is therefore advisable that you consult with your supervisor and closely examine examples from other theses and published studies to get a sense of the requirements in your field. In general terms, however, a good research question should be:

- Relevant: It must clearly relate to the problems or issues that the project seeks to address.
- Important: It should address a key problem in the field (see From identifying a gap to constructing a problem above).
- Clear: It should be expressed using concise language and contain no ambiguity.
- Precise: What is being investigated should be clearly specified.
- Researchable: The information and sources required to answer the question must exist and you must be able to access them (with the exception of data that you will generate yourself through surveys, experiments, etc.).

In cases where there is more than one research question, the questions must be clearly related to each other so that they add up to a coherent whole.

2.1 Constructing a Research Question

The wording of your research question (or questions) is important because it will direct your approach and writing and help to shape the feedback that you receive from readers of your proposal. It is important to understand that you can change your research question at a later date if you think that the wording needs to be changed or if you make discoveries that encourage a different approach to the topic.

It is highly likely, in fact, that the question that you pose in your proposal will be different from the question or questions that your thesis actually answers.

Wording of research questions can vary significantly from one field of study to another, so it is advisable that you consult with your supervisor and seek out examples from other research proposals, theses, or published papers. However, the following general points can be made:

- How and why questions are usually preferred as they generate analytical rather than descriptive findings.
- The question should be worded in such a way that a number of different responses would be possible.
- The wording should be neutral in tone. Avoid value judgements or untested assumptions.
- The wording should include the key concepts and relationships that you have identified.

2.2 Interrogate Research Question

After the initial drafting of your research question you should interrogate it to highlight strengths and weaknesses in your thinking or wording. Write responses to the following questions:

- Does this research question interest me? Will it sustain my interest?
- Does this question help to address a significant research problem?
- Has this question already been answered by others? If so, how will my response differ?
- Is the question too easy to answer? Is the answer too obvious?
- Can the question be approached from different angles?
- Will this question allow me to generate a strong and interesting position or findings? At this point in time what hypothesis would I make in response to the question?
- Does the question have an appropriate scope? Is the specified content too broad or too narrow? Is the question researchable?
- What kind of information and sources will I need to answer the question? Am I able to access this information? Will I need to generate my own data?
- What about the ethics of the question? Does it entail risks for the researcher or (if relevant) the participants?

3 Literature Review

The literature review surveys key academic works in your field of research, such as books, refereed journal articles, and postgraduate theses. The review should summarise, analyse, categorise and compare the most significant works - it does not need to cover everything that has been written on the topic. Most importantly, it should clearly demonstrate the gap or problem that your research project will address by outlining both the strengths and the limitations of previous research.

3.1 Planning and Writing a Literature Review

There are three main considerations when writing a literature review for a research proposal:

- **Focus:** A literature review for a research project should give an accurate picture of the general field, but rather than discuss every text in detail it should focus on works that are directly related to your specific topic. It is usually best to focus on the most prominent and recent contributions to the topic.
- **Structure:** Rather than discuss each selected text separately, a literature review should be organised around key similarities, differences, and other points that you want to make about the development of academic writing on the topic. Search for a review article on the topic (a kind of literature review found in refereed journals) and study the literature reviews contained in recently published books and journal articles on the topic. Consider how these authors categorise and evaluate the literature.
- **Faculty/School specifics:** The above points apply for most research proposals, but some faculties and schools will have their own requirements regarding the content and word count of the literature review component. This will have an influence on how you select and critique the literature. It is therefore important that you check the specific requirements of your Faculty or School.

3.2 Brainstorming for a Literature Review

A useful way to generate ideas for your literature review is to brainstorm the key scholars, texts, arguments, sources and methods that are related to your research topic. Write down responses to the following questions. Your answers might take the form of brief dot points or you might prefer to write more extensive responses. Extensive responses are often a useful way of thinking through a question or issue that you find challenging:

- Have scholars attempted to address the research gap or problem that I intend to explore?
 - If so, how have they attempted to address it? Can I place them into different categories?

- If not, why not?
- How and why are the approaches of key scholars similar? How and why are their approaches different?

Consider similarities and differences in:

- Theoretical frameworks
- The sources and data used
- Research methods (e.g. quantitative, qualitative, experimental, mixed-method)
- What are the strengths of research on this topic?
- What are the limitations, gaps and weaknesses in the field?

4 Project Design

In this section of your proposal you will need to answer three questions:

- What kind of data or sources will you use?
- How will you collect and manage this material?
- Which theoretical and methodological techniques will you use to interpret and analyse these data/sources?

It is important that you explain the design of your project in a clear and logical way. Your reader should be able to clearly see what you will do and how will you do it, and how this combination of data/sources and methods will allow you to address your research problem.

4.1 Tips for completing the study/project design component

The most important thing to keep in mind about the study/project design component is that it should not simply consist of a list of tasks that will be undertaken. Above all, it needs to establish that these tasks constitute the most effective way of exploring the research problem.

The key to composing a clear and focused study/project design is to show how you are building upon and/or departing from the theoretical and methodological approaches of key scholars in the field. It is therefore necessary to:

- Consider the theories and methods that other researchers have used, and;
- Consider the theories and methods that have not been used (or that have been underutilised) but perhaps could be.

When writing up your study/project design, be specific about:

- The methods that you will use to gather your information;
- The theories and techniques you will use to analyse the information
- The relevance of these approaches to your research problem

Specify the particular activities that you will undertake and show how they will contribute to the investigation of your research problem (e.g. I will engage in a close content analysis of political satire in order to show how it subverts the visual and rhetorical tropes of serious political discourse).

Finally, anticipate any potential barriers that you will face in carrying out your research design. No method is perfect, so you need to describe what the shortcomings will be and explain how you will address them.

4.2 Brainstorm your study design

The following questions will help you to formulate your study/project design. You might find it useful to organise your responses into a table, mind-map, or flow-chart (see example below). Many researchers prefer this approach as it allows them to visualise their project in its entirety, and draw connections between data and research goals that they may not have previously considered.

- What is your research problem?
- What are the specific research goals or questions that you will need to address in order to investigate this problem?
- What kind of data or sources will best allow you to reach these goals?
- How will you gather your data/sources/information? How will you gain access to them? Will you need to generate your own data by conducting surveys or experiments?
- What method or methods of interpretation and analysis is most suitable for your project? Will your study be qualitative, quantitative, or mixed-method?
- What theories underlie your research? How will these theories allow you to meet your research goals?
- Are there any ethical implications of your data collection or method of analysis?

5 Timeline

The timeline demonstrates to the reader that your project can be completed within the period of candidature. The timeline should consist of a series of goals that you will need to meet in order to complete all aspects of your thesis, from initial research to the final editing, with an expected date of completion for each step. It should also contain a statement of the progress that you have made to date. The timeline should also factor in other research related activities such as conferences and publications (if applicable).

The timeline is not a static document; you will need to update it regularly.

6 Expected Outcomes and Impacts

Conclude your research proposal by stating your expected outcomes. At this stage in the research process, what arguments and conclusions do you expect to reach? Your reader will understand that these are projected outcomes based on the extent of research at the time of writing, and that they will almost certainly change in the light of further research. It is essential, however, that you give your reader a sense of what conclusions may be drawn. This will allow your reader to further assess the significance and validity of your project. It will also indicate to your reader that you have thought ahead and considered the potential outcomes and implications of your research.

To avoid repetition with the description of your research aims and significance earlier in the proposal, focus on how you envisage your research will contribute to debates and trends in your field. What impact might your findings have on how the problem is perceived? What impact might your methods have on how research is conducted in the future?
